Interpretation of Sequences

The set of all possible sequences $\{x[n, \zeta]\}$ is called an **ensemble**, and each individual sequence $x[n, \zeta_k]$, corresponding to a specific value of $\zeta = \zeta_k$, is called a **realisation** or a **sample sequence** of the ensemble.

Interpretation of Sequences

The set of all possible sequences $\{x[n, \zeta]\}$ is called an **ensemble**, and each individual sequence $x[n, \zeta_k]$, corresponding to a specific value of $\zeta = \zeta_k$, is called a **realisation** or a **sample sequence** of the ensemble.

There are four possible interpretations of $x[n, \zeta]$:

	ζ Fixed	ζ Variable
n Fixed	Number	Random variable
n Variable	Sample sequence	Stochastic process

Interpretation of Sequences

The set of all possible sequences $\{x[n, \zeta]\}$ is called an **ensemble**, and each individual sequence $x[n, \zeta_k]$, corresponding to a specific value of $\zeta = \zeta_k$, is called a **realisation** or a **sample sequence** of the ensemble.

There are four possible interpretations of $x[n, \zeta]$:

	ζ Fixed	ζ Variable
n Fixed	Number	Random variable
n Variable	Sample sequence	Stochastic process

Use simplified notation $x[n] \equiv x[n, \zeta]$ to denote both a stochastic process, and a single realisation. Use the terms **random process** and **stochastic process** interchangeably throughout this course.

Linear Systems Theory

Linear Signal Models

Predictable Processes

The unpredictability of a random process is, in general, the combined result of the following two characteristics:

1. The selection of a single realisation is based on the outcome of a random experiment;
2. No functional description is available for *all* realisations of the *ensemble*.

Predictable Processes

The unpredictability of a random process is, in general, the combined result of the following two characteristics:

1. The selection of a single realisation is based on the outcome of a random experiment;
2. No functional description is available for *all* realisations of the *ensemble*.

In some special cases, however, a functional relationship is available. This means that after the occurrence of all samples of a particular realisation up to a particular point, n , all future values can be predicted exactly from the past ones.

Predictable Processes

The unpredictability of a random process is, in general, the combined result of the following two characteristics:

1. The selection of a single realisation is based on the outcome of a random experiment;
2. No functional description is available for *all* realisations of the *ensemble*.

In some special cases, however, a functional relationship is available. This means that after the occurrence of all samples of a particular realisation up to a particular point, n , all future values can be predicted exactly from the past ones.

If this is the case for a random process, then it is called **predictable**, otherwise it is said to be **unpredictable** or a **regular process**.

Linear Systems Theory

Linear Signal Models

Description using pdfs

For fixed $n = n_0$, $x[n_0, \zeta]$ is a random variable. Moreover, the random vector formed from the k random variables $\{x[n_j], j \in \{1, \dots, k\}\}$ is characterised by the cumulative distribution function (cdf) and pdfs:

$$F_X(x_1 \dots x_k | n_1 \dots n_k) = \Pr(x[n_1] \leq x_1, \dots, x[n_k] \leq x_k)$$

$$f_X(x_1 \dots x_k | n_1 \dots n_k) = \frac{\partial^k F_X(x_1 \dots x_k | n_1 \dots n_k)}{\partial x_1 \dots \partial x_k}$$

Linear Systems Theory

Linear Signal Models

Description using pdfs

For fixed $n = n_0$, $x[n_0, \zeta]$ is a random variable. Moreover, the random vector formed from the k random variables $\{x[n_j], j \in \{1, \dots, k\}\}$ is characterised by the cdf and pdfs:

$$F_X(x_1 \dots x_k | n_1 \dots n_k) = \Pr(x[n_1] \leq x_1, \dots, x[n_k] \leq x_k)$$

$$f_X(x_1 \dots x_k | n_1 \dots n_k) = \frac{\partial^k F_X(x_1 \dots x_k | n_1 \dots n_k)}{\partial x_1 \dots \partial x_k}$$

In exactly the same way as with random variables and random vectors, it is:

- difficult to estimate these probability functions without considerable additional information or assumptions;
- possible to frequently characterise stochastic processes usefully with much less information.

Linear Signal Models

Mean and Variance Sequence At time n , the ensemble mean and variance are given by:

$$\mu_x[n] = \mathbb{E} [x[n]]$$

$$\sigma_x^2[n] = \mathbb{E} [|x[n] - \mu_x[n]|^2] = \mathbb{E} [|x[n]|^2] - |\mu_x[n]|^2$$

Both $\mu_x[n]$ and $\sigma_x^2[n]$ are deterministic sequences.

Linear Systems Theory

Linear Signal Models

Second-order Statistical Description

Mean and Variance Sequence At time n , the ensemble mean and variance are given by:

$$\mu_x[n] = \mathbb{E} [x[n]]$$

$$\sigma_x^2[n] = \mathbb{E} [|x[n] - \mu_x[n]|^2] = \mathbb{E} [|x[n]|^2] - |\mu_x[n]|^2$$

Both $\mu_x[n]$ and $\sigma_x^2[n]$ are deterministic sequences.

Autocorrelation sequence The second-order statistic $r_{xx}[n_1, n_2]$ provides a measure of the dependence between values of the process at two different times; it can provide information about the time variation of the process:

$$r_{xx}[n_1, n_2] = \mathbb{E} [x[n_1] x^*[n_2]]$$

Second-order Statistical Description

Autocovariance sequence The autocovariance sequence provides a measure of how similar the deviation from the mean of a process is at two different time instances:

$$\begin{aligned}\gamma_{xx}[n_1, n_2] &= \mathbb{E} [(x[n_1] - \mu_x[n_1])(x[n_2] - \mu_x[n_2])^*] \\ &= r_{xx}[n_1, n_2] - \mu_x[n_1] \mu_x^*[n_2]\end{aligned}$$

Second-order Statistical Description

Autocovariance sequence The autocovariance sequence provides a measure of how similar the deviation from the mean of a process is at two different time instances:

$$\begin{aligned}\gamma_{xx}[n_1, n_2] &= \mathbb{E} [(x[n_1] - \mu_x[n_1])(x[n_2] - \mu_x[n_2])^*] \\ &= r_{xx}[n_1, n_2] - \mu_x[n_1] \mu_x^*[n_2]\end{aligned}$$

To show how these deterministic sequences of a stochastic process can be calculated, several examples are considered in detail below.

Example of calculating autocorrelations

Power Spectral Density

Linear Systems Theory

Linear Signal Models

Example ([Manolakis:2000, Ex 3.9, page 144]). The harmonic process $x[n]$ is defined by:

$$x[n] = \sum_{k=1}^M A_k \cos(\omega_k n + \phi_k), \quad \omega_k \neq 0$$

where M , $\{A_k\}_1^M$ and $\{\omega_k\}_1^M$ are constants, and $\{\phi_k\}_1^M$ are pairwise independent random variables uniformly distributed in the interval $[0, 2\pi]$.

1. Determine the mean of $x(n)$.
2. Show the autocorrelation sequence is given by

$$r_{xx}[\ell] = \frac{1}{2} \sum_{k=1}^M |A_k|^2 \cos \omega_k \ell, \quad -\infty < \ell < \infty \quad \boxtimes$$

Example of calculating autocorrelations

Example ([Manolakis:2000, Ex 3.9, page 144]). SOLUTION. 1. The expected value of the process is straightforwardly given by:

$$\mathbb{E} [x(n)] = \mathbb{E} \left[\sum_{k=1}^M A_k \cos(\omega_k n + \phi_k) \right] = \sum_{k=1}^M A_k \mathbb{E} [\cos(\omega_k n + \phi_k)]$$

Since a co-sinusoid is zero-mean, then:

$$\mathbb{E} [\cos(\omega_k n + \phi_k)] = \int_0^{2\pi} \cos(\omega_k n + \phi_k) \times \frac{1}{2\pi} \times d\phi_k = 0$$

Hence, it follows:

$$\mathbb{E} [x(n)] = 0, \quad \forall n \quad \square$$

Power Spectral Density

Linear Systems Theory

Linear Signal Models

Example of calculating autocorrelations

Example ([Manolakis:2000, Ex 3.9, page 144]). SOLUTION. 1.

$$r_{xx}(n_1, n_2) = \mathbb{E} \left[\sum_{k=1}^M A_k \cos(\omega_k n_1 + \phi_k) \sum_{j=1}^M A_j^* \cos(\omega_j n_2 + \phi_j) \right]$$

$$= \sum_{k=1}^M \sum_{j=1}^M A_k A_j^* \mathbb{E} [\cos(\omega_k n_1 + \phi_k) \cos(\omega_j n_2 + \phi_j)]$$

After some algebra, it can be shown that:

$$\mathbb{E} [\cos(\omega_k n_1 + \phi_k) \cos(\omega_j n_2 + \phi_j)] = \begin{cases} \frac{1}{2} \cos \omega_k (n_1 - n_2) & k = j \\ 0 & \text{otherwise} \end{cases}$$

where $g(\phi_k) = \cos(\omega_k n_1 + \phi_k)$ and $h(\phi_k) = \cos(\omega_j n_2 + \phi_j)$, and the fact that ϕ_k and ϕ_j are independent implies the expectation function may be factorised.

Independence A stochastic process is independent if, and only if, (iff)

$$f_X(x_1, \dots, x_N | n_1, \dots, n_N) = \prod_{k=1}^N f_{X_k}(x_k | n_k)$$

$\forall N, n_k, k \in \{1, \dots, N\}$. Here, therefore, $x(n)$ is a sequence of independent random variables.

Independence A stochastic process is independent iff

$$f_X(x_1, \dots, x_N | n_1, \dots, n_N) = \prod_{k=1}^N f_{X_k}(x_k | n_k)$$

$\forall N, n_k, k \in \{1, \dots, N\}$. Here, therefore, $x(n)$ is a sequence of independent random variables.

An independent and identically distributed (i. i. d.) process is one where all the random variables $\{x(n_k, \zeta), n_k \in \mathbb{Z}\}$ have the same pdf, and $x(n)$ will be called an **i. i. d.** random process.

Linear Signal Models

Independence A stochastic process is independent iff

$$f_X(x_1, \dots, x_N | n_1, \dots, n_N) = \prod_{k=1}^N f_{X_k}(x_k | n_k)$$

$\forall N, n_k, k \in \{1, \dots, N\}$. Here, therefore, $x(n)$ is a sequence of independent random variables.

An i. i. d. process is one where all the random variables $\{x(n_k, \zeta), n_k \in \mathbb{Z}\}$ have the same pdf, and $x(n)$ will be called an **i. i. d.** random process.

An uncorrelated processes is a sequence of uncorrelated random variables:

$$\gamma_{xx}(n_1, n_2) = \sigma_x^2(n_1) \delta(n_1 - n_2)$$

Types of Stochastic Processes

An **orthogonal process** is a sequence of **orthogonal random variables**, and is given by:

$$r_{xx}(n_1, n_2) = \mathbb{E} [|x(n_1)|^2] \delta(n_1 - n_2)$$

If a process is zero-mean, then it is both **orthogonal** and **uncorrelated** since $\gamma_{xx}(n_1, n_2) = r_{xx}(n_1, n_2)$.

Types of Stochastic Processes

An **orthogonal process** is a sequence of **orthogonal random variables**, and is given by:

$$r_{xx}(n_1, n_2) = \mathbb{E} [|x(n_1)|^2] \delta(n_1 - n_2)$$

If a process is zero-mean, then it is both **orthogonal** and **uncorrelated** since $\gamma_{xx}(n_1, n_2) = r_{xx}(n_1, n_2)$.

A **stationary process** is a random process where its statistical properties do not vary with time. Processes whose statistical properties **do** change with time are referred to as **nonstationary**.

Stationary Processes

A random process $x(n)$ has been called **stationary** if its statistics determined for $x(n)$ are equal to those for $x(n + k)$, for every k . There are various formal definitions of **stationarity**, along with **quasi-stationary** processes, which are discussed below.

- **Order- N and strict-sense stationarity**
- **Wide-sense stationarity**
- **Wide-sense periodicity and cyclo-stationarity**
- **Local- or quasi-stationary processes**

After this, some examples of various stationary processes will be given.

Linear Signal Models

Order- N and strict-sense stationarity

Definition (Stationary of order- N). A stochastic process $x(n)$ is called stationary of order- N if:

$$f_X(x_1, \dots, x_N | n_1, \dots, n_N) = f_X(x_1, \dots, x_N | n_1 + k, \dots, n_N + k) \quad \diamond$$

for any value of k . If $x(n)$ is stationary for all orders $N \in \mathbb{Z}^+$, it is said to be **strict-sense stationary (SSS)**.

Linear Systems Theory

Linear Signal Models

Order- N and strict-sense stationarity

Definition (Stationary of order- N). A stochastic process $x(n)$ is called stationary of order- N if:

$$f_X(x_1, \dots, x_N | n_1, \dots, n_N) = f_X(x_1, \dots, x_N | n_1 + k, \dots, n_N + k) \quad \diamond$$

for any value of k . If $x(n)$ is stationary for all orders $N \in \mathbb{Z}^+$, it is said to be **SSS**.

An independent and identically distributed process is SSS since, in this case, $f_{X_k}(x_k | n_k) = f_X(x_k)$ is independent of n , and therefore also of $n + k$.

However, SSS is more restrictive than necessary in practical applications, and is a rarely required property.

Power Spectral Density

Linear Systems Theory

Linear Signal Models

Wide-sense stationarity

A more relaxed form of stationarity, which is sufficient for practical problems, occurs when a random process is stationary order-2; such a process is **wide-sense stationary (WSS)**.

Linear Signal Models

Wide-sense stationarity

Definition (Wide-sense stationarity). A random signal $x(n)$ is called wide-sense stationary if:

- the mean and variance is constant and independent of n :

$$\mathbb{E} [x(n)] = \mu_x$$

$$\text{var} [x(n)] = \sigma_x^2$$

- the autocorrelation depends only on the time difference $l = n_1 - n_2$, called the lag:

$$r_{xx}(n_1, n_2) = r_{xx}^*(n_2, n_1) = \mathbb{E} [x(n_1) x^*(n_2)]$$

$$= r_{xx}(l) = r_{xx}(n_1 - n_2) = \mathbb{E} [x(n_1) x^*(n_1 - l)] \quad \diamond$$

$$= \mathbb{E} [x(n_2 + l) x^*(n_2)]$$

Wide-sense stationarity

- The autocovariance function is given by:

$$\gamma_{xx}(l) = r_{xx}(l) - |\mu_x|^2$$

- Since 2nd-order moments are defined in terms of 2nd-order pdf, then strict-sense stationary are always WSS, but not necessarily *vice-versa*, except if the signal is Gaussian.
- In practice, however, it is very rare to encounter a signal that is stationary in the wide-sense, but not stationary in the strict sense.

Linear Signal Models

Wide-sense cyclo-stationarity

Two classes of **nonstationary process** which, in part, have properties resembling stationary signals are:

1. A **wide-sense periodic (WSP) process** is classified as signals whose mean is periodic, and whose autocorrelation function is periodic in both dimensions:

$$\begin{aligned}\mu_x(n) &= \mu_x(n + N) \\ r_{xx}(n_1, n_2) &= r_{xx}(n_1 + N, n_2) = r_{xx}(n_1, n_2 + N) \\ &= r_{xx}(n_1 + N, n_2 + N)\end{aligned}$$

for all n , n_1 and n_2 . These are quite tight constraints for real signals.

Power Spectral Density

Linear Systems Theory

Linear Signal Models

Wide-sense cyclo-stationarity

2. A wide-sense cyclo-stationary process has similar but less restrictive properties than a WSP process, in that the mean is periodic, but the autocorrelation function is now just invariant to a shift by N in both of its arguments:

$$\mu_x(n) = \mu_x(n + N)$$

$$r_{xx}(n_1, n_2) = r_{xx}(n_1 + N, n_2 + N)$$

for all n, n_1 and n_2 . This type of nonstationary process has more practical applications, as the following example will show.

Quasi-stationarity

At the introduction of this lecture course, it was noted that in the analysis of speech signals, the speech waveform is broken up into short segments whose duration is typically 10 to 20 milliseconds.

This is because speech can be modelled as a **locally stationary** or **quasi-stationary** process.

Such processes possess statistical properties that change *slowly* over short periods of time.

They are *globally* nonstationary, but are approximately *locally* stationary, and are modelled as if the statistics *actually are* stationary over a short segment of time.

WSS Properties

The average power of a WSS process $x(n)$ satisfies:

$$r_{xx}(0) = \sigma_x^2 + |\mu_x|^2$$

$$r_{xx}(0) \geq r_{xx}(l), \quad \text{for all } l$$

The average power of a WSS process $x(n)$ satisfies:

$$r_{xx}(0) = \sigma_x^2 + |\mu_x|^2$$

$$r_{xx}(0) \geq r_{xx}(l), \quad \text{for all } l$$

The expression for power can be broken down as follows:

$$\text{Average DC Power: } |\mu_x|^2$$

$$\text{Average AC Power: } \sigma_x^2$$

$$\text{Total average power: } r_{xx}(0)$$

Total average power = Average DC power + Average AC power

WSS Properties

The average power of a WSS process $x(n)$ satisfies:

$$r_{xx}(0) = \sigma_x^2 + |\mu_x|^2$$

$$r_{xx}(0) \geq r_{xx}(l), \quad \text{for all } l$$

The expression for power can be broken down as follows:

Average DC Power: $|\mu_x|^2$

Average AC Power: σ_x^2

Total average power: $r_{xx}(0)$

Total average power = Average DC power + Average AC power

Moreover, it follows that $\gamma_{xx}(0) \geq \gamma_{xx}(l)$.

It is left as an exercise to show that the autocorrelation sequence $r_{xx}(l)$ is:

- a conjugate symmetric function of the lag l :

$$r_{xx}^*(-l) = r_{xx}(l)$$

- a nonnegative-definite or positive semi-definite function, such that for any sequence $\alpha(n)$:

$$\sum_{n=1}^M \sum_{m=1}^M \alpha^*(n) r_{xx}(n-m) \alpha(m) \geq 0$$

Note that, more generally, even a correlation function for a nonstationary random process is **positive semi-definite**:

$$\sum_{n=1}^M \sum_{m=1}^M \alpha^*(n) r_{xx}(n, m) \alpha(m) \geq 0 \quad \text{for any sequence } \alpha(n)$$

Estimating statistical properties

- A stochastic process consists of the ensemble, $x(n, \zeta)$, and a probability law, $f_X(\{x\} | \{n\})$. If this information is available $\forall n$, the statistical properties are easily determined.

Ensemble and Time-Averages

Ensemble averaging, as considered so far in the course, is not frequently used in practice since it is impractical to obtain the number of realisations needed for an accurate estimate.

A statistical average that can be obtained from a **single** realisation of a process is a **time-average**, defined by:

$$\langle g(x(n)) \rangle \triangleq \lim_{N \rightarrow \infty} \frac{1}{2N + 1} \sum_{n=-N}^N g(x(n))$$

For every ensemble average, a corresponding time-average can be defined; the above corresponds to: $\mathbb{E} [g(x(n))]$.

Ensemble and Time-Averages

Ensemble averaging, as considered so far in the course, is not frequently used in practice since it is impractical to obtain the number of realisations needed for an accurate estimate.

A statistical average that can be obtained from a **single** realisation of a process is a **time-average**, defined by:

$$\langle g(x(n)) \rangle \triangleq \lim_{N \rightarrow \infty} \frac{1}{2N + 1} \sum_{n=-N}^N g(x(n))$$

For every ensemble average, a corresponding time-average can be defined; the above corresponds to: $\mathbb{E} [g(x(n))]$.

Time-averages are random variables since they implicitly depend on the particular realisation, given by ζ . Averages of deterministic signals are fixed numbers or sequences, even though they are given by the same expression.

Linear Systems Theory

Linear Signal Models

Ergodicity

A stochastic process, $x(n)$, is **ergodic** if its ensemble averages can be estimated from a single realisation of a process using time averages.

The two most important degrees of ergodicity are:

Mean-Ergodic (or ergodic in the mean) processes have identical expected values and sample-means:

$$\langle x(n) \rangle = \mathbb{E} [x(n)]$$

Covariance-Ergodic Processes (or ergodic in correlation) have the property that:

$$\langle x(n) x^*(n-l) \rangle = \mathbb{E} [x(n) x^*(n-l)]$$

Power Spectral Density

Linear Systems Theory

Linear Signal Models

Ergodicity

- It should be intuitiveness obvious that ergodic processes must be stationary and, moreover, that a process which is ergodic both in the mean and correlation is WSS.
- WSS processes are not necessarily ergodic.
- Ergodic is often used to mean both ergodic in the mean and correlation.
- In practice, only finite records of data are available, and therefore an estimate of the time-average will be given by

$$\langle g(x(n)) \rangle = \frac{1}{N} \sum_{n \in \mathcal{N}} g(x(n))$$

where N is the number of data-points available. The performance of this estimator will be discussed later in this course.

Cross-correlation and cross-covariance A measure of the dependence between values of two *different* stochastic processes is given by the **cross-correlation** and **cross-covariance** functions:

$$r_{xy}(n_1, n_2) = \mathbb{E} [x(n_1) y^*(n_2)]$$

$$\gamma_{xy}(n_1, n_2) = r_{xy}(n_1, n_2) - \mu_x(n_1) \mu_y^*(n_2)$$

Cross-correlation and cross-covariance A measure of the dependence between values of two *different* stochastic processes is given by the **cross-correlation** and **cross-covariance** functions:

$$r_{xy}(n_1, n_2) = \mathbb{E} [x(n_1) y^*(n_2)]$$

$$\gamma_{xy}(n_1, n_2) = r_{xy}(n_1, n_2) - \mu_x(n_1) \mu_y^*(n_2)$$

Normalised cross-correlation (or cross-covariance) The cross-covariance provides a measure of similarity of the deviation from the respective means of two processes. It makes sense to consider this deviation relative to their **standard deviations**; thus, **normalised cross-correlations**:

$$\rho_{xy}(n_1, n_2) = \frac{\gamma_{xy}(n_1, n_2)}{\sigma_x(n_1) \sigma_y(n_2)}$$

Linear Signal Models

Statistically independence of two stochastic processes occurs when, for every n_x and n_y ,

$$f_{XY}(x, y | n_x, n_y) = f_X(x | n_x) f_Y(y | n_y)$$

Uncorrelated stochastic processes have, for all n_x & $n_y \neq n_x$:

$$\gamma_{xy}(n_x, n_y) = 0$$

$$r_{xy}(n_x, n_y) = \mu_x(n_x) \mu_y(n_y)$$

Types of Joint Stochastic Processes

Statistically independence of two stochastic processes occurs when, for every n_x and n_y ,

$$f_{XY}(x, y | n_x, n_y) = f_X(x | n_x) f_Y(y | n_y)$$

Uncorrelated stochastic processes have, for all n_x & $n_y \neq n_x$:

$$\gamma_{xy}(n_x, n_y) = 0$$

$$r_{xy}(n_x, n_y) = \mu_x(n_x) \mu_y(n_y)$$

Joint stochastic processes that are statistically independent are uncorrelated, but not necessarily vice-versa, except for Gaussian processes. Nevertheless, a measure of uncorrelatedness is often used as a measure of independence. More on this later.

Linear Systems Theory

Linear Signal Models

Orthogonal joint processes have, for every n_1 and $n_2 \neq n_1$:

$$r_{xy}(n_1, n_2) = 0$$

Joint WSS is similar to WSS for a single stochastic process, and is useful since it facilitates a spectral description, as discussed later in this course:

$$r_{xy}(l) = r_{xy}(n_1 - n_2) = r_{yx}^*(-l) = \mathbb{E} [x(n) y^*(n - l)]$$

$$\gamma_{xy}(l) = \gamma_{xy}(n_1 - n_2) = \gamma_{yx}^*(-l) = r_{xy}(l) - \mu_x \mu_y^*$$

Joint-Ergodicity applies to two ergodic processes, $x(n)$ and $y(n)$, whose ensemble cross-correlation can be estimated from a time-average:

$$\langle x(n) y^*(n - l) \rangle = \mathbb{E} [x(n) y^*(n - l)]$$

Correlation Matrices

Let an M -dimensional random vector $\mathbf{X}(n, \zeta) \equiv \mathbf{X}(n)$ be derived from the random process $x(n)$ as follows:

$$\mathbf{X}(n) \triangleq \begin{bmatrix} x(n) & x(n-1) & \cdots & x(n-M+1) \end{bmatrix}^T$$

Correlation Matrices

For stationary processes, the correlation matrix has an interesting additional structure. Note that:

1. $\mathbf{R}_X(n)$ is a constant matrix \mathbf{R}_X ;
2. $r_{xx}(n-i, n-j) = r_{xx}(j-i) = r_{xx}(l), l = j-i$;
3. conjugate symmetry gives $r_{xx}(l) = r_{xx}^*(-l)$.

A powerful model for a stochastic process known as a **Markov model** is introduced; such a process that satisfies this model is known as a **Markov process**.

Quite simply, a Markov process is one in which the probability of any particular value in a sequence is dependent upon the preceding sample values.

The simplest kind of dependence arises when the probability of any sample depends only upon the value of the *immediately preceding* sample, and this is known as a **first-order Markov process**.

This simple process is a surprisingly good model for a number of practical signal processing, communications and control problems.

Markov Processes

As an example of a Markov process, consider the process generated by the difference equation

$$x(n) = -a x(n - 1) + w(n)$$

where a is a known constant, and $w(n)$ is a sequence of zero-mean i. i. d. Gaussian random variables with variance σ_W^2 density:

$$f_W(w(n)) = \frac{1}{\sqrt{2\pi\sigma_W^2}} \exp\left\{-\frac{w(n)^2}{2\sigma_W^2}\right\}$$

where a is a known constant, and $w(n)$ is a sequence of zero-mean i. i. d. Gaussian random variables with variance σ_W^2 density:

$$f_W(w(n)) = \frac{1}{\sqrt{2\pi\sigma_W^2}} \exp\left\{-\frac{w(n)^2}{2\sigma_W^2}\right\}$$

The conditional density of $x(n)$ given $x(n-1)$ is also Gaussian,

$$f_X(x(n) | x(n-1)) = \frac{1}{\sqrt{2\pi\sigma_W^2}} \exp\left\{-\frac{(x(n) + ax(n-1))^2}{2\sigma_W^2}\right\}$$

Markov Processes

Definition (Markov Process). A random process is a P th-order Markov process if the distribution of $x(n)$, given the infinite past, depends only on the previous P samples $\{x(n-1), \dots, x(n-P)\}$; that is, if:

$$f_X(x(n) | x(n-1), x(n-2), \dots) = f_X(x(n) | x(n-1), \dots, x(n-P))$$

Frequency- and transform-domain methods are very powerful tools for the analysis of deterministic sequences. It seems natural to extend these techniques to analysis stationary **random processes**.

So far in this course, **stationary stochastic processes** have been considered in the time-domain through the use of the **ACF**.

Since the ACF for a stationary process is a function of a single-discrete time process, then the question arises as to what the DTFT corresponds to.

It turns out to be known as the **power spectral density (PSD)** of a stationary random process, and the PSD is an extremely powerful and conceptually appealing tool in statistical signal processing.

Linear Signal Models

Introduction

In signal theory for deterministic signals, spectra are used to represent a function as a superposition of exponential functions. For random signals, the notion of a spectrum has two interpretations:

Transform of averages The first involves transform of averages (or moments). As will be seen, this will be the Fourier transform of the autocorrelation function.

Stochastic decomposition The second interpretation represents a stochastic process as a superposition of exponentials, where the coefficients are themselves random variables. Hence, $x(n)$ can be represented as:

$$x(n) = \frac{1}{2\pi} \int_{-\pi}^{\pi} X(e^{j\omega}) e^{j\omega n} d\omega, \quad n \in \mathbb{R}$$

where $X(e^{j\omega})$ is a random variable for a given value of ω .

The power spectral density

The discrete-time Fourier transform of the autocorrelation function of a stationary stochastic process $x[n, \zeta]$ is known as the **power spectral density (PSD)**, is denoted by $P_{xx}(e^{j\omega})$, and is given by:

$$P_{xx}(e^{j\omega}) = \sum_{\ell \in \mathbb{Z}} r_{xx}[\ell] e^{-j\omega\ell}$$

where ω is frequency in radians per sample.

- Introduction
- **The power spectral density**
- Properties of the **power spectral density**

- Complex Spectral Density Functions

The power spectral density

The discrete-time Fourier transform of the autocorrelation function of a stationary stochastic process $x[n, \zeta]$ is known as the **power spectral density (PSD)**, is denoted by $P_{xx}(e^{j\omega})$, and is given by:

$$P_{xx}(e^{j\omega}) = \sum_{\ell \in \mathbb{Z}} r_{xx}[\ell] e^{-j\omega\ell}$$

where ω is frequency in radians per sample.

The autocorrelation function, $r_{xx}[\ell]$, can be recovered from the **PSD** by using the **inverse-DTFT**:

$$r_{xx}[\ell] = \frac{1}{2\pi} \int_{-\pi}^{\pi} P_{xx}(e^{j\omega}) e^{j\omega\ell} d\omega, \quad \ell \in \mathbb{Z}$$

Linear Signal Models

General form of the PSD

A process, $x(n)$, and therefore its corresponding autocorrelation function (ACF), $r_{xx}(l)$, can always be decomposed into a zero-mean aperiodic component, $r_{xx}^{(a)}(l)$, and a non-zero-mean periodic component, $r_{xx}^{(p)}(l)$:

$$r_{xx}(l) = r_{xx}^{(a)}(l) + r_{xx}^{(p)}(l)$$

- Introduction

General form of the PSD

A process, $x(n)$, and therefore its corresponding autocorrelation function (ACF), $r_{xx}(l)$, can always be decomposed into a zero-mean aperiodic component, $r_{xx}^{(a)}(l)$, and a non-zero-mean periodic component, $r_{xx}^{(p)}(l)$:

$$r_{xx}(l) = r_{xx}^{(a)}(l) + r_{xx}^{(p)}(l)$$

Theorem (PSD of a non-zero-mean process with periodic component).
The most general definition of the PSD for a non-zero-mean stochastic process with a periodic component is

$$P_{xx}(e^{j\omega}) = P_{xx}^{(a)}(e^{j\omega}) + \frac{2\pi}{K} \sum_{k \in \mathcal{K}} P_{xx}^{(p)}(k) \delta(\omega - \omega_k) \quad \diamond$$

$P_{xx}^{(a)}(e^{j\omega})$ is the DTFT of $r_{xx}^{(a)}(l)$, while $P_{xx}^{(p)}(k)$ are the discrete Fourier transform (DFT) coefficients for $r_{xx}^{(p)}(l)$.

- The cross-power spectral density
- Complex Spectral Density Functions

The cross-power spectral density

The cross-power spectral density (CPSD) of two jointly stationary stochastic processes, $x(n)$ and $y(n)$, provides a description of their statistical relations in the frequency domain.

It is defined, naturally, as the DTFT of the cross-correlation, $r_{xy}(\ell) \triangleq \mathbb{E} [x(n) y^*(n - \ell)]$:

$$P_{xy}(e^{j\omega}) = \mathcal{F}\{r_{xy}(\ell)\} = \sum_{l \in \mathbb{Z}} r_{xy}(\ell) e^{-j\omega l}$$

- Introduction

- Complex Spectral Density Functions

The cross-power spectral density

The cross-power spectral density (CPSD) of two jointly stationary stochastic processes, $x(n)$ and $y(n)$, provides a description of their statistical relations in the frequency domain.

It is defined, naturally, as the DTFT of the cross-correlation, $r_{xy}(\ell) \triangleq \mathbb{E} [x(n) y^*(n - \ell)]$:

$$P_{xy}(e^{j\omega}) = \mathcal{F}\{r_{xy}(\ell)\} = \sum_{l \in \mathbb{Z}} r_{xy}(\ell) e^{-j\omega l}$$

The cross-correlation $r_{xy}(\ell)$ can be recovered by using the inverse-DTFT:

$$r_{xy}(\ell) = \frac{1}{2\pi} \int_{-\pi}^{\pi} P_{xy}(e^{j\omega}) e^{j\omega l} d\omega, \quad l \in \mathbb{R}$$

- Introduction
- The power spectral density
- Properties of the power spectral density

The cross-power spectral density

The cross-power spectral density (CPSD) of two jointly stationary stochastic processes, $x(n)$ and $y(n)$, provides a description of their statistical relations in the frequency domain.

It is defined, naturally, as the DTFT of the cross-correlation, $r_{xy}(\ell) \triangleq \mathbb{E} [x(n) y^*(n - \ell)]$:

$$P_{xy}(e^{j\omega}) = \mathcal{F}\{r_{xy}(\ell)\} = \sum_{l \in \mathbb{Z}} r_{xy}(\ell) e^{-j\omega l}$$

The cross-correlation $r_{xy}(l)$ can be recovered by using the inverse-DTFT:

$$r_{xy}(l) = \frac{1}{2\pi} \int_{-\pi}^{\pi} P_{xy}(e^{j\omega}) e^{j\omega l} d\omega, \quad l \in \mathbb{R}$$

The cross-spectrum $P_{xy}(e^{j\omega})$ is, in general, a complex function of ω .

- Introduction
- The power spectral density
- Properties of the power spectral density
- General form of the PSD
- The cross-power spectral density
- Complex Spectral Density Functions

The cross-power spectral density

Some properties of the CPSD and related definitions include:

1. $P_{xy}(e^{j\omega})$ is periodic in ω with period 2π .

2. Since $r_{xy}(l) = r_{yx}^*(-l)$, then it follows:

$$P_{xy}(e^{j\omega}) = P_{yx}^*(e^{j\omega})$$

3. If the process $x(n)$ is real, then $r_{xy}(l)$ is real, and:

$$P_{xy}(e^{j\omega}) = P_{xy}^*(e^{-j\omega})$$

4. The **coherence function**, is given by:

$$\Gamma_{xy}(e^{j\omega}) \triangleq \frac{P_{xy}(e^{j\omega})}{\sqrt{P_{xx}(e^{j\omega})} \sqrt{P_{yy}(e^{j\omega})}}$$

Linear Signal Models

LTI Systems with Stationary Inputs

Since each sequence (realisation) of a stochastic process is a deterministic signal, there is a well-defined input signal producing a well-defined output signal corresponding to a single realisation of the output stochastic process:

$$y(n, \zeta) = \sum_{k=-\infty}^{\infty} h(k) x(n - k, \zeta)$$

- A complete description of $y(n, \zeta)$ requires the computation of an infinite number of convolutions, corresponding to each value of ζ .
- Thus, a better description would be to consider the statistical properties of $y(n, \zeta)$ in terms of the statistical properties of the input and the characteristics of the system.

Linear Signal Models

LTI Systems with Stationary Inputs

To investigate the statistical input-output properties of a linear system, note the following fundamental theorem:

Theorem (Expectation in Linear Systems). For any linear system,

$$\mathbb{E} [L[x(n)]] = L[\mathbb{E} [x(n)]]$$

In other words, the mean $\mu_y(n)$ of the output $y(n)$ equals the response of the system to the mean $\mu_x(n)$ of the input:

$$\mu_y(n) = L[\mu_x(n)]$$

Linear Signal Models

Input-output Statistics of a LTI System

If a stationary stochastic process $x[n]$ with mean value μ_x and correlation $r_{xx}[\ell]$ is applied to the input of a LTI system with impulse response $h[n]$ and transfer function $H(e^{j\omega})$, then the:

Output mean value is given by:

$$\mu_y = \mu_x \sum_{k=-\infty}^{\infty} h[k] = \mu_x H(e^{j0})$$

Input-output cross-correlation is given by:

$$r_{xy}[\ell] = h^*[-\ell] * r_{xx}[\ell] = \sum_{k=-\infty}^{\infty} h^*[-k] r_{xx}[\ell - k]$$

Similarly, it follows that $r_{yx}(l) = h(l) * r_{xx}(l)$.

- LTI Systems with Stationary Inputs
- Input-output Statistics of a LTI System
- **System identification**
- LTV Systems with Nonstationary Inputs
- Difference Equation
- Frequency-Domain Analysis of LTI systems

System identification

System identification by cross-correlation.

The system is excited with a white Gaussian noise (WGN) input with autocorrelation function:

$$r_{xx}(l) = \delta(l)$$

Since the output-input cross-correlation can be written as:

$$r_{yx}(l) = h(l) * r_{xx}(l)$$

then, with $r_{xx}(l) = \delta(l)$, it follows:

$$r_{yx}(l) = h(l) * \delta(l) = h(l)$$

Linear Signal Models

General LTV system with nonstationary input

The input and output are related by the generalised convolution:

$$y(n) = \sum_{k=-\infty}^{\infty} h(n, k) x(k)$$

where $h(n, k)$ is the response at time-index n to an impulse occurring at the system input at time-index k .

Linear Signal Models

Consider a LTI system that can be represented by a difference equation:

$$\sum_{p=0}^P a_p y(n-p) = \sum_{q=0}^Q b_q x(n-q)$$

where $a_0 \triangleq 1$.

Assuming that both $x(n)$ and $y(n)$ are stationary processes, then taking expectations of both sides gives,

$$\mu_y = \frac{\sum_{q=0}^Q b_q}{1 + \sum_{p=1}^P a_p} \mu_x$$

Difference Equation

Next, multiplying the system equation throughout by $y^*(m)$ and taking expectations gives:

$$\sum_{p=0}^P a_p r_{yy}(n-p, m) = \sum_{q=0}^Q b_q r_{xy}(n-q, m)$$

Linear Signal Models

Difference Equation

Example ([Manolakis:2000, Example 3.6.2, Page 141]). Let $x(n)$ be a random process generated by the first order difference equation given by:

$$x(n) = \alpha x(n-1) + w(n), \quad |\alpha| \leq 1, n \in \mathbb{Z} \quad \boxtimes$$

where $w(n) \sim \mathcal{N}(\mu_w, \sigma_w^2)$ is an i. i. d. WGN process.

- Demonstrate that the process $x(n)$ is stationary, and determine the mean μ_x .
- Determine the autocovariance and autocorrelation function, $\gamma_{xx}(l)$ and $r_{xx}(l)$.

The Ubiquitous WGN Sequence

The simplest random signal model is the WSS WGN sequence:

$$w(n) \sim \mathcal{N}(0, \sigma_w^2)$$

The sequence is i. i. d., and $P_{ww}(e^{j\omega}) = \sigma_w^2$, $-\pi < \omega \leq \pi$. It is also easy to generate samples using simple algorithms.

Filtration of WGN

By filtering a WGN through a stable LTI system, it is possible to obtain a stochastic signal at the output with almost any arbitrary aperiodic correlation function or continuous PSD.

Random signals with line PSDs can be generated by using the **harmonic process** model, which is a linear combination of sinusoidal sequences with statistically independent random phases. Signal models with mixed PSDs can be obtained by combining these two models; a process justified by the **Wold decomposition**.

Nonparametric and parametric models

Nonparametric models have no restriction on its form, or the number of parameters characterising the model. For example, specifying a LTI filter by its impulse response is a nonparametric model.

Parametric models, on the other hand, describe a system with a finite number of parameters. For example, if a LTI filter is specified by a finite-order rational **system function**, it is a parametric model.

Nonparametric and parametric models

Nonparametric models have no restriction on its form, or the number of parameters characterising the model. For example, specifying a LTI filter by its impulse response is a nonparametric model.

Parametric models, on the other hand, describe a system with a finite number of parameters. For example, if a LTI filter is specified by a finite-order rational **system function**, it is a parametric model.

Two important analysis tools present themselves for parametric modelling:

1. given the model parameters, analyse the characteristics of that model (in terms of moments etc.);
2. design of a parametric system model to produce a random signal with a specified **autocorrelation** function or PSD.

This is **signal modelling**.

Parametric Pole-Zero Signal Models

Consider a system described by the following linear constant-coefficient difference equation:

$$x(n) = - \sum_{k=1}^P a_k x(n-k) + \sum_{k=0}^Q d_k w(n-k)$$

Taking z -transforms gives the system function:

$$H(z) = \frac{X(z)}{W(z)} = \frac{\sum_{k=0}^Q d_k z^{-k}}{1 + \sum_{k=1}^P a_k z^{-k}}$$
$$\triangleq \frac{D(z)}{A(z)} = G \frac{\prod_{k=1}^Q (1 - z_k z^{-1})}{\prod_{k=1}^P (1 - p_k z^{-1})}$$

This system has Q zeros, $\{z_k, k \in \mathcal{Q}\}$ where $\mathcal{Q} = \{1, \dots, Q\}$, and P poles, $\{p_k, k \in \mathcal{P}\}$. The term G is the system gain.

Types of pole-zero models

If a parametric model is *excited* with WGN, the resulting output signal has second-order moments determined by the parameters of the model.

These **stochastic processes** have special names in the literature, and are known as:

a moving average (MA) process when it is the output of an all-zero model;

an autoregressive (AR) process when it is the output of an all-pole model;

an autoregressive moving average (ARMA) process when it is the output of an pole-zero model;

each subject to a WGN process at the input.

All-pole Models

All-pole models are frequently used in signal processing applications since they are:

- mathematically convenient since model parameters can be estimated by solving a set of linear equations, and
- they widely parsimoniously approximate rational transfer functions, especially resonant systems.

All-pole Models

All-pole models are frequently used in signal processing applications since they are:

- mathematically convenient since model parameters can be estimated by solving a set of linear equations, and
- they widely parsimoniously approximate rational transfer functions, especially resonant systems.

There are various model properties of the all-pole model that are useful; these include:

1. the systems impulse response;
2. the autocorrelation of the impulse response;
3. and minimum-phase conditions.

Frequency Response of an All-Pole Filter

The all-pole model has form:

$$H(z) = \frac{d_0}{A(z)} = \frac{d_0}{1 + \sum_{k=1}^P a_k z^{-k}} = \frac{d_0}{\prod_{k=1}^P (1 - p_k z^{-1})}$$

and therefore its frequency response is given by:

$$H(e^{j\omega}) = \frac{d_0}{1 + \sum_{k=1}^P a_k e^{-jk\omega}} = \frac{d_0}{\prod_{k=1}^P (1 - p_k e^{-j\omega})}$$

Frequency Response of an All-Pole Filter

The all-pole model has form:

$$H(z) = \frac{d_0}{A(z)} = \frac{d_0}{1 + \sum_{k=1}^P a_k z^{-k}} = \frac{d_0}{\prod_{k=1}^P (1 - p_k z^{-1})}$$

and therefore its frequency response is given by:

$$H(e^{j\omega}) = \frac{d_0}{1 + \sum_{k=1}^P a_k e^{-jk\omega}} = \frac{d_0}{\prod_{k=1}^P (1 - p_k e^{-j\omega})}$$

When each of the poles are written in the form $p_k = r_k e^{j\omega_k}$, then the frequency response can be written as:

$$H(e^{j\omega}) = \frac{d_0}{\prod_{k=1}^P (1 - r_k e^{-j(\omega - \omega_k)})}$$

Hence, it can be deduced that resonances occur near the frequencies corresponding to the phase position of the poles.

Frequency Response of an All-Pole Filter

Hence, the PSD of the output of an all-pole filter is given by:

$$P_{xx}(e^{j\omega}) = \sigma_w^2 |H(e^{j\omega})|^2 = \frac{G^2}{\prod_{k=1}^P |1 - r_k e^{-j(\omega - \omega_k)}|^2}$$

where $G = \sigma_w d_0$ is the overall gain of the system.

Frequency Response of an All-Pole Filter

Hence, the PSD of the output of an all-pole filter is given by:

$$P_{xx}(e^{j\omega}) = \sigma_w^2 |H(e^{j\omega})|^2 = \frac{G^2}{\prod_{k=1}^P |1 - r_k e^{-j(\omega - \omega_k)}|^2}$$

where $G = \sigma_w d_0$ is the overall gain of the system.

Consider the all-pole model with poles at positions:

$$\{p_k\} = \{r_k e^{j\omega_k}\} \quad \text{where} \quad \begin{cases} \{r_k\} &= \{0.985, 0.951, 0.942, 0.933\} \\ \{\omega_k\} &= 2\pi \times \{270, 550, 844, 1131\}/2450; \end{cases}$$

Impulse Response of an All-Pole Filter

The impulse response of the all-pole filter satisfies the equation:

$$h(n) = - \sum_{k=1}^P a_k h(n-k) + d_0 \delta(n)$$

If $H(z)$ has its poles inside the unit circle, then $h(n)$ is a causal, stable sequence, and the system is **minimum-phase**.

Assuming causality, such that $h(n) = 0, n < 0$ then it follows $h(-k) = 0, k > 0$, and therefore:

$$h(n) = \begin{cases} 0 & \text{if } n < 0 \\ d_0 & \text{if } n = 0 \\ - \sum_{k=1}^P a_k h(n-k) & \text{if } n > 0 \end{cases}$$

All-Pole Modelling and Linear Prediction

A **linear predictor** forms an estimate, or *prediction*, $\hat{x}(n)$, of the present value of a stochastic process $x(n)$ from a linear combination of the past P samples; that is:

$$\hat{x}(n) = - \sum_{k=1}^P a_k x(n-k)$$

The coefficients $\{a_k\}$ of the linear predictor are determined by attempting to minimise some function of the **prediction error** given by:

$$e(n) = x(n) - \hat{x}(n)$$

Usually the objective function is equivalent to mean-squared error (MSE), given by $E = \sum_n e^2(n)$.

All-Pole Modelling and Linear Prediction

Hence, the prediction error can be written as:

$$e(n) = x(n) - \hat{x}(n) = x(n) + \sum_{k=1}^P a_k x(n - k)$$

All-Pole Modelling and Linear Prediction

Hence, the prediction error can be written as:

$$e(n) = x(n) - \hat{x}(n) = x(n) + \sum_{k=1}^P a_k x(n-k)$$

- Thus, the prediction error is equal to the excitation of the all-pole model; $e(n) = w(n)$. Clearly, **finite impulse response (FIR) linear prediction** and **all-pole modelling** are closely related.
- Many of the properties and algorithms developed for either **linear prediction** or **all-pole modelling** can be applied to the other.

Autoregressive Processes

Multiply the difference through by $x^*(n-l)$ and take expectations to obtain:

$$r_{xx}(l) + \sum_{k=1}^P a_k r_{xx}(l-k) = r_{wx}(l)$$

Observing that $x(n)$ cannot depend on future values of $w(n)$ since the system is causal, then $r_{wx}(l) = \mathbb{E}[w(n)x^*(n-l)]$ is zero if $l > 0$, and σ_w^2 if $l = 0$.

Autoregressive Processes

Multiply the difference through by $x^*(n - l)$ and take expectations to obtain:

$$r_{xx}(l) + \sum_{k=1}^P a_k r_{xx}(l - k) = r_{wx}(l)$$

Thus, writing Equation ?? for $l = \{0, 1, \dots, P\}$

matrix-vector form (noting that $r_{xx}(l) = r_{xx}^*(-l)$ and that the parameters $\{a_k\}$ are real) as:

$$\begin{bmatrix} r_{xx}(0) & r_{xx}^*(1) & \dots & r_{xx}^*(P) \\ r_{xx}(1) & r_{xx}(0) & \dots & r_{xx}^*(P-1) \\ \vdots & \vdots & \ddots & \vdots \\ r_{xx}(P) & r_{xx}(P-1) & \dots & r_{xx}^*(0) \end{bmatrix} \begin{bmatrix} 1 \\ a_1 \\ \vdots \\ a_P \end{bmatrix} = \begin{bmatrix} \sigma_w^2 \\ 0 \\ \vdots \\ 0 \end{bmatrix}$$

All-Zero models

Whereas **all-pole** models can capture resonant features of a particular PSD, it cannot capture *nulls* in the frequency response. These can only be modelled using a pole-zero or **all-zero** model.

The output of an all-zero model is the weighted average of delayed versions of the input signal. Thus, assume an all-zero model of the form:

$$x(n) = \sum_{k=0}^Q d_k w(n-k)$$

where Q is the order of the model, and the corresponding system function is given by:

$$H(z) = D(z) = \sum_{k=0}^Q d_k z^{-k}$$

The all-zero model has form:

$$H(z) = D(z) = \sum_{k=0}^Q d_k z^{-k} = d_0 \prod_{k=1}^Q (1 - z_k z^{-1})$$

Therefore, its frequency response is given by:

$$H(e^{j\omega}) = \sum_{k=0}^Q d_k e^{-jk\omega} = d_0 \prod_{k=1}^Q (1 - z_k e^{-j\omega})$$

Frequency Response of an All-Zero Filter

The all-zero model has form:

$$H(z) = D(z) = \sum_{k=0}^Q d_k z^{-k} = d_0 \prod_{k=1}^Q (1 - z_k z^{-1})$$

Therefore, its frequency response is given by:

$$H(e^{j\omega}) = \sum_{k=0}^Q d_k e^{-jk\omega} = d_0 \prod_{k=1}^Q (1 - z_k e^{-j\omega})$$

When each of the zeros are written in the form $z_k = r_k e^{j\omega_k}$, then the frequency response can be written as:

$$H(e^{j\omega}) = d_0 \prod_{k=1}^Q (1 - r_k e^{-j(\omega - \omega_k)})$$

Hence, it can be deduced that troughs or nulls occur near frequencies corresponding to the phase position of the zeros.

Pole-Zero Models

The output of a causal pole-zero model is given by the recursive input-output relationship:

$$x[n] = - \sum_{k=1}^P a_k x[n - k] + \sum_{k=0}^Q d_k w[n - k]$$

The corresponding system function is given by:

$$H(z) = \frac{D(z)}{A(z)} = \frac{\sum_{k=0}^Q d_k z^{-k}}{1 + \sum_{k=1}^P a_k z^{-k}}$$

Pole-Zero Frequency Response

The pole-zero model can be written as

$$H(z) = \frac{D(z)}{A(z)} = d_0 \frac{\prod_{k=1}^Q (1 - z_k z^{-1})}{\prod_{k=1}^P (1 - p_k z^{-1})}$$

Therefore, its frequency response is given by:

$$H(e^{j\omega}) = d_0 \frac{\prod_{k=1}^Q (1 - z_k e^{-j\omega})}{\prod_{k=1}^P (1 - p_k e^{-j\omega})}$$
